ABSTRACT— In this paper, an enhancement design of communication system using optical radio frequency (RF) waves in free space optical communication (FSO) system is presented. To our knowledge, it is the first time that the effect of Gamma-Gamma turbulent channel model on the performance of the proposed system is analyzed and simulated. To obtain an optical communication system with good performance and high spectrum efficiency, we proposed two types of optical RF waves including optical single sideband (OSSB) and optical double sideband (ODSB). This strategy that integrated an optical communication system with turbulent channel model can express an accurate model of optical and RF waves propagation in free space. Performance of the system under different regimes, weak, moderate and strong turbulent is studied considering several parameters like max quality factor, bit error rates (BER), and optical signal-to-noise ratio (OSNR). Also, a comparative study between two methods of optical RF waves is presented.

KEYWORDS: FSO, OSNR, OSSB, ODSB, Gamma-Gamma turbulent model, BER.

I. INTRODUCTION

The technology of free space optical communication (FSO) is offered a system with Gigabit data rate and Ethernet throughput including data, voice and video. Recently, FSO has possessed for several interested features such as high speed transmission data, high bandwidth, low cost and low installation [1-3]. FSO technology for propagation of optical or microwave signals over atmosphere

is suffering from variant and random refractive index. This problem decreases the performance of system as well as bit error rate (BER) and optical signal-to-noise ratio (OSNR). In outstretching technology of optical communication system, several systems use the radio-over-fiber (ROF) technology. The main purpose of this method is integration with other networks and low dispersion [4-5]. But, integration the radio frequency (RF) wave with FSO system is hardly affected by the atmosphere turbulent that is one of the advantage of radio over free space communication [6]. Also, the propagated optical beam through the atmosphere can be scattered and absorbed by different atmosphere condition. The interaction between optical or RF waves with turbulence can be degraded the phase and amplitude of received waves. In order to model the turbulent channel of FSO systems several methods including long normal, negative exponential and Gamma-Gamma channel model are presented [7-9]. In [10], several types of optical RF waves including optical single sideband (OSSB), optical double sideband (ODSB) and optical-carrier-suppression (OCS) are proposed. These methods can be considered using direct and external modulation. Direct modulation with laser source is simpler than external modulation, but it has drawbacks of limited transmission of data rate and limited bandwidth. A radio over free space optical communication system with different channel model is presented in [11]. The system only analyzed the optical spectrum of waves before and after the free space channel. In [12], BER

performance of binary phase shift keying (BPSK) modulation in FSO link based on long-normal turbulent channel model is simulated.

In this paper, a new optical communication system with two types of optical RF waves, OSSB and ODSB, by considering the effect of Gamma-Gamma turbulent channel model is introduced. In weak and moderate regimes, two types of optical RF waves have good performance, but in strong regime the ODSB waves has a better operation rather than OSSB wave.

The rest of the paper is organized as follows: in section 2 and 3 the Gamma-Gamma turbulent model of free space channel and generation of optical RF waves are explained. Proposed system and simulation results are expressed in section 4. Finally we conclude the paper in section 5.

II. GAMMA-GAMMA TURBULENT CHANNEL MODEL

The performance of FSO link is affected with atmosphere turbulence which causes some changes in refractive index. The model of turbulent channel is very complex and depended on the earth's surface that can be studied in weak, moderate and strong regimes. One of the turbulent channel models is Gamma-Gamma model which is operated based on modulation processes. The Gamma-Gamma turbulent channel model can be modeled by received irradiance I [13]:

$$I = I_x I_y \tag{1}$$

where I_x and I_y are large and small scale of turbulent eddies, respectively. Also, the probability density function (PDF) of received irradiance distribution function is given as [13]:

$$P(I) = \frac{2(\alpha\beta)^{(\alpha+\beta)/2}}{\Gamma(\alpha)+\Gamma(\beta)} I^{(\alpha+\beta)/2} K_{\alpha-\beta}(2\sqrt{\alpha\beta I}) \tag{2}$$

where $K_n(0)$ is the modified Bessel function of second kind of order n . α and β are the

parameters of Gamma-Gamma distribution related to large-scale and small-scale scintillation, respectively, and $\Gamma(0)$ is the Gamma function assuming that the optical radiation is a plan wave. Also, α and β are given by [13]:

$$\alpha = \left\{ \exp \left[\frac{0.4\sigma_R^2}{(1+1.11\sigma_R^2)^{7/6}} \right] - 1 \right\}^{-1} \tag{3}$$

$$\beta = \left\{ \exp \left[\frac{0.51\sigma_R^2}{(1+0.69\sigma_R^{12/5})^{5/6}} \right] - 1 \right\}^{-1} \tag{4}$$

where σ_R^2 is the long irradiance variance and given as [14]:

$$\sigma_R^2 = 1.23c_n^2 k^{7/6} L^{11/6} \tag{5}$$

where L is the link path, $k = 2\pi/\lambda$, is the wave number and c_n^2 is the refractive index structure. The PDF of $P(I)$ versus irradiance, I , for different regime and σ_R^2 is shown in Fig. 1.

Fig. 1. PDF of the proposed system versus the irradiance.

Table 1. Different parameters, used in the Gamma-Gamma model

parameter	weak	moderate	strong
A	11.651	4.026	4.225
B	10.153	1.976	1.484
σ_R^2	0.2	1.6	3.5
c_n^2	7.5×10^{-17}	3.6×10^{-15}	1.7×10^{-13}

Table 1 summarized the different parameters of the Gamma-Gamma turbulent channel

model in different regimes such as weak, moderate and strong.

III. GENERATION OF OPTICAL RF WAVES

To generate the optical RF waves, two methods of direct and external modulation can be used. Direct modulation unlike external modulation has several restrictions such as low data rate (less than 1 Gbps) and low modulation bandwidth of laser source. Also, one of the advantage of external modulation is low nonlinear effects of modulator. Based on mentioned reasons, we proposed the external modulation for our presented system. Figure 2 shows the configuration of ODSB and OSSB scheme. Mach-Zehnder modulator (MZM) was biased with RF input signal and laser used as optical carrier wave [14].

Fig. 2. Configuration of the proposed optical RF waves, (a) ODSB wave, (b) OSSB wave.

Figure 3 shows the optical spectrum output of MZM for proposed optical RF waves. It is clear that ODSB wave has higher power than OSSB wave. So, in the next section we try to demonstrate that the performance of ODSB wave is better than OSSB wave in the proposed system.

Fig. 3. Optical output spectra of MZM for ODSB and OSSB waves.

IV. PROPOSED SYSTEM AND SIMULATION RESULTS

The block diagram of the proposed system is shown in Fig. 4. The presented system consists of optical RF waves that are prepared in section III. Optical RF waves have been transmitted through the atmosphere channel and detected by the receiver unit. The transmitted unit uses a single wavelength continuous-wave (CW) laser at 193.1 THz consider into account ODSB format. Figure 5 shows the block diagram of the receiver unit that consist of optical filter (OF), optical amplifier (OA), PIN photodiode (PIN PD), amplitude modulation (AM) and analyzer. In Table II, the setup parameters of the proposed system are shown. The link distance of the proposed system is 1500 m that operates at 10 Gbps rate.

Table 2. Maximum quality factor and minimum BER at different regimes

Gamma-Gamma condition	Q		BER	
	OSSB	ODSB	OSSB	ODSB
Weak	12.108	15.15	5.37×10^{-34}	2.93×10^{-52}
Moderate	8.83	12.12	2.36×10^{-21}	3.37×10^{-34}
Strong	2.82	4.19	2.2×10^{-3}	1.31×10^{-5}

Turbulent channel model and optical RF waves are considered simultaneously for simulation of the proposed system, at clear weather atmosphere with 0.18 dB attenuation. Eye diagram and max quality factor of the proposed system, versus time, are shown in Fig. 6, for two ODSB and OSSB schemes at 10 Gbps rate. It is obvious that ODSB wave

has better performance and max quality in different regimes. Table III shows the results of the presented system including max quality factor, min BER and OSNR at different regimes.

Fig. 4. Overall block diagram of the proposed system.

Fig. 5. The block diagram of the receiver (OA: optical amplifier, OF: optical filter, PD: photodetector, AM: amplitude modulation).

A comparison between min BER, max quality factor and OSNR for two methods shows that ODSB waves have better performance than OSSB waves at different regimes. For example results at moderate regime ODSB shows 12.12 max quality factor, 3.37×10^{-34} min BER and 46.85 OSNR, also for OSSB at this regime max quality, min BER and OSNR are 8.83, 2.36×10^{-21} and 46.6, respectively. Figure 7 and Fig. 8 show OSNR, and Min log BER of the proposed system versus input powers for OSSB and ODSB schemes. It is illustrated that by enhancement of the input power OSNR of the system will be improved and the Min log BER is reduced in two proposed methods. However, increasing the value of input power can increase insertion loss of the system. Also the results show that at weak regime the

variation is less than moderate and strong turbulent channel model.

Fig. 6. The eye diagram and quality factor, Q of (a) OSSB and (b) OSDB at 10 Gbps.

Fig. 7. (a) OSNR, and (b) Min log BER in OSSB wave versus input power of the system.

In our future works, we try to design and analyze the presented system with Dense Wavelength Division Multiplexing (DWDM) system and different channel model to achieve next generation networks.

Fig. 8. (a) OSNR, (b) Min log BER in ODSB wave versus input power of the system.

Table 3. The maximum quality factor and minimum BER for different atmospheric conditions

Gamma-Gamma condition	Q		BER		OSNR	
	OSSB	ODSB	OSSB	ODSB	OSSB	ODSB
Weak	12.108	15.15	5.37×10^{-34}	2.93×10^{-52}	47.35	48.71
Moderate	8.83	12.12	2.36×10^{-21}	3.37×10^{-34}	46.6	46.85
Strong	2.82	4.19	2.2×10^{-3}	1.31×10^{-5}	39.59	39.61

V. CONCLUSION

In this paper, we have proposed and analyzed a new design of optical microwave over free space communication system by taking into account Gamma-Gamma turbulent channel model and attenuation loss. The proposed system is simulated and enhanced to obtain min BER and OSNR, and max quality factor at 10 Gbps through a 1500 m distance link with two methods of optical RF waves, OSSB and ODSB. From the simulation results we understand that ODSB wave has better performance for proposed system rather than OSSB wave at different regimes. A system with these features is suitable for using in the wireless communication systems.
